Portfolio review

Kappa Foundation | Working material for the final group assignment | 25 October 2026

Our recommendation

We would keep the stock weights selected on 31 December 2022. The revised trustee payments make the bond funding decision more important, but we have not found enough improvement from optimizing the stock weights again to justify replacing the frozen portfolio. Principal matching is our cautious funding reference. Coupon funding is worth considering, since it increases the money available for growth, but it leaves almost no cash just after the 2025 payment. The group still needs to choose between them.

The revised schedule moves USD 1.2 million of the learning-centre payment from December 2027 to December 2025. Total promised payments stay at USD 6 million.

Plan	Cost of bonds	Net equity after 10 bp fee	Cash in 2030	Equity CAGR needed
Original	USD 5,764,524	USD 6,229,247	USD 630,000	4.66%
Revised principal	USD 5,784,228	USD 6,209,562	USD 564,000	4.80%
Revised coupon	USD 5,429,776	USD 6,563,660	USD 168,000	4.63%

These growth hurdles use a 2.3% annual inflation assumption and the 2030 real purchasing-power target of USD 8 million in 2022 dollars. They are not forecasts of future investment performance.

Why retain the stocks?

The candidate list contains ten common stocks across five sectors plus two US equity ETFs. The selected allocation actually buys eight individual stocks: AAPL, MSFT, JPM, JNJ, PFE, PG, KO and CAT. It does not hold either ETF. That is an important concentration risk even though the candidate list is broader.

We used 96 common monthly returns from 2015 to 2022, with expected returns based on 25% own-stock history and 75% of a VTI market prior. The model limits any direct stock to 15%, any direct-stock sector to 30%, each ETF to 30% and the combined ETF allocation to 40%. We compared Sample Mean-Variance with a Single-Index version and a constrained Minimum Variance alternative. We also tested foundation risk aversion at A = 3 and A = 6.

Under revised principal funding, reoptimization only increases the modeled equity utility from 0.053328705 to 0.053328718 at A = 3. Under revised coupon funding it rises from 0.055826785 to 0.055830594. We judge the gains too small to make a confident case for changing the frozen weights. Against the fixed Minimum Variance alternative, the preference would change at about A = 8.94 under principal funding or A = 8.46 under coupon funding. These are comparisons between fixed stock portfolios, not cutoffs for a fully reoptimized fund.

With a 25% instantaneous equity fall and a parallel 100 basis point bond-rate increase, the starting fund would lose roughly 14.42% under revised principal funding and 15.08% under revised coupon funding. These shocks are not the 12-month withdrawal-adjusted measures used for the trustees' 12% warning and 15% review levels.

What we learned from the actual market test

The frozen equity position was evaluated from the 3 January 2023 closing-price proxy to the final trading date of 2025, without discretionary rebalancing. Both the selected shares and VTI were charged the same 10 basis point starting cost. The archived Yahoo source contains nine original responses, 752 shared trading dates and 36 monthly observations.

Observed growth measure	Selected stocks	VTI
CAGR after entry fee	17.69%	22.45%
Annualized volatility	11.80%	12.60%
Largest monthly NAV drawdown	-8.70%	-9.11%
End-2025 growth value	USD 10.15m	USD 11.43m

The annualized arithmetic active return is -4.11%, with 6.91% tracking error. The chosen stocks delivered a positive return but did not beat the simpler benchmark. We cannot use this future period to revise what the team knew in December 2022.

The JNJ/Kenvue separation was an optional exchange. Our frozen policy does not elect the exchange or add any KVUE shares. Using JNJ closing prices and ordinary cash dividends instead of adjusted prices changes the portfolio's final value by only about USD 188. This supports our treatment, but the final check of dividend timing and action mechanics remains a human responsibility.

What the factor regressions add

The group's factor analysis used the same 96 historical months. For the growth portfolio, adjusted R-squared rises from about 0.785 with CAPM to 0.844 with the Fama-French three-factor model. Market beta is around 0.867 and the SMB loading is around -0.426, consistent with a large-company tilt. The sample's positive monthly alpha is not evidence of a reliable future abnormal return. Microsoft's exposure to market risk is stronger than Procter & Gamble's; PG's historical factor alpha is not statistically distinguishable from zero. Keeping the same normalized stock weights under different bond funding leaves these historical stock-factor estimates unchanged.

Checks, files and open decisions

The supporting Python runs from saved data without internet and covers three funding plans, five stock portfolios per plan, a 36-case inflation and cash-buffer comparison, the bond cash-flow ledger and the 2023 to 2025 observed returns. The original selection is kept separate from the later evaluation.

For the group handoff, the Portfolio Final folder contains a PDF report, an editable Word copy, a nine-sheet workbook and saved Yahoo data. Portfolio Files.zip contains the same material. The historical model, original 2022 decision, bond analysis, factor data and Python scripts stay in their existing repository folders so the group does not have to manage duplicate copies.

We have completed the stock calculations, compared both revised funding plans, checked the payment cash flows, and tested the frozen portfolio against actual market data. The remaining decisions are for the group to make: which bond plan to recommend, how to document the university submission, and how to combine this section with the final committee memo and presentation.

The 22 October course-submission email is documented, but we cannot independently confirm the university's acceptance or hash every member of the emailed ZIP. The observed figures therefore remain conditional on original-submission verification. The course's complete final archive is a group responsibility; this portfolio handoff should not be described as that archive.
